Tomography appears in adaptive optics

- ▶ Modern telescope imaging suffers from turbulence in the atmosphere
⇒ blurring of images
- ▶ Adaptive optics corrects the perturbed incoming light in real-time
- ▶ Major challenge in wide-field AO:
atmospheric tomography

Application: dental implant planning, where a missing tooth is replaced with an implant

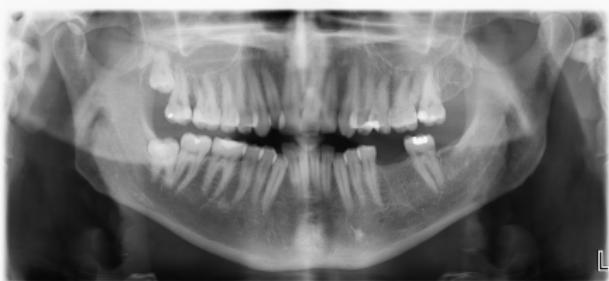

This is the classical imaging procedure
of the panoramic X-ray device

The resulting image shows a sharp layer positioned inside the dental arc

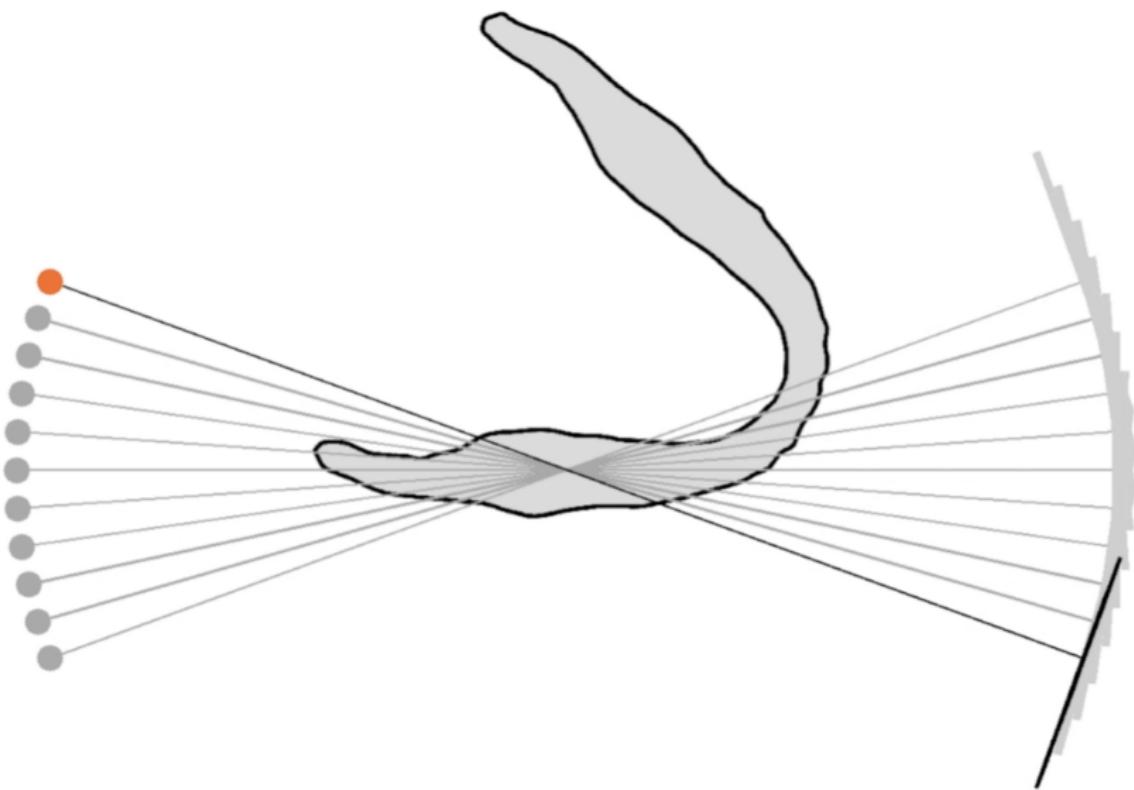

Nowadays, a digital panoramic imaging device is standard equipment at dental clinics

A panoramic dental image offers a general overview showing all teeth and other structures simultaneously.

Panoramic images are not suitable for dental implant planning because of unavoidable geometric distortion.

We reprogram the panoramic X-ray device so that it collects projection data by scanning

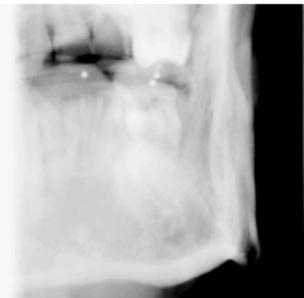

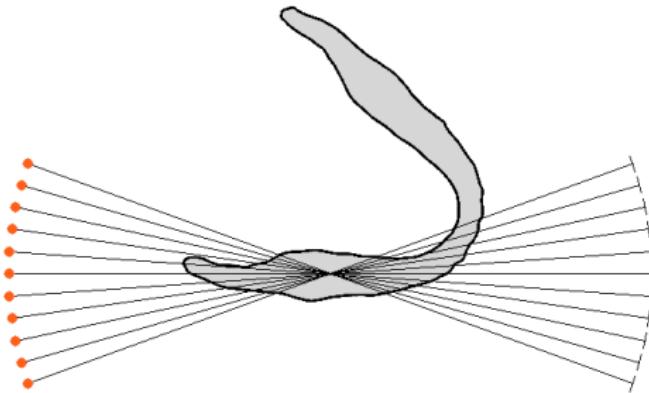

We reprogram the panoramic X-ray device so that it collects projection data by scanning

Number of projection images: 11

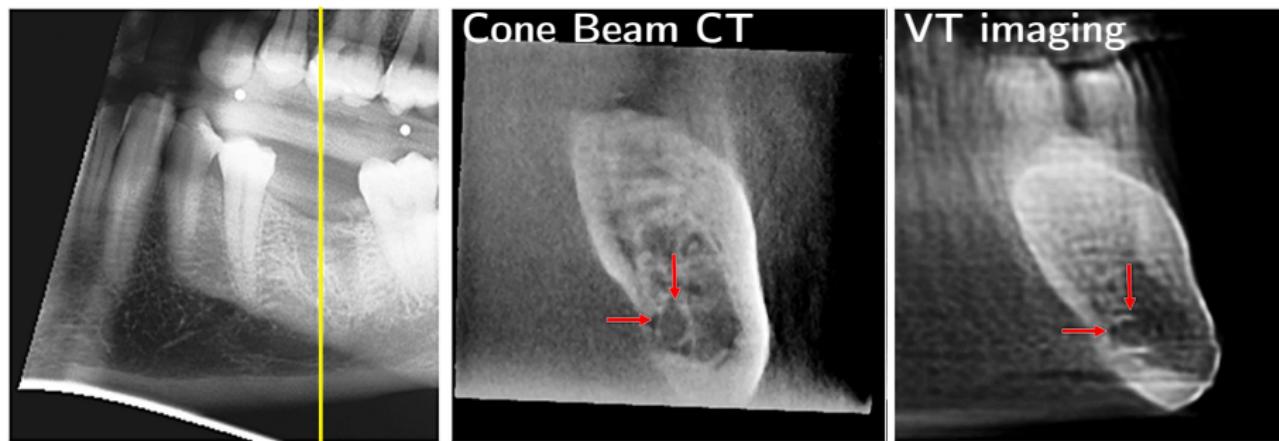

Angle of view: 40 degrees

Image size: 1000×1000 pixels

The unknown vector f has
7 000 000 elements.

Standard Cone Beam CT reconstruction delivers 100 times more radiation than VT imaging

A
of
Continuous
Theory

Definition of the Radon transform

Let $f(x) = f(x_1, x_2)$ be the X-ray attenuation coefficient. The classical model for tomographic data is the **Radon transform**

$$Rf(\theta, s) = \int_{x \cdot \vec{\theta} = s} f(x) dx = \int_{\tau \in \mathbb{R}} f(s\vec{\theta} + \tau\vec{\theta}^\perp) d\tau, \quad \vec{\theta} \in S^1, s \in \mathbb{R},$$

where S^1 is the unit circle, $\vec{\theta}^\perp$ is a unit vector perpendicular to the unit vector $\vec{\theta} = (\cos \theta, \sin \theta)$, and $x \cdot \vec{\theta}$ denotes vector inner product.

Note that f is defined on \mathbb{R}^2 and Rf is defined on $S^1 \times \mathbb{R}^1$.

The Fourier slice theorem

Let $f : \mathbb{R}^2 \rightarrow \mathbb{R}$ be smooth and compactly supported. Denote $R_\theta f(s) := Rf(\theta, s)$ for $\vec{\theta} \in S^1$ and $s \in \mathbb{R}$. Then

$$\widehat{R_\theta f}(\xi) = \widehat{f}(\xi \vec{\theta}).$$

Proof. The change of coordinates $x = s\vec{\theta} + \tau\vec{\theta}^\perp$ gives $s = \vec{\theta} \cdot x$ and $dx = d\tau ds$. Calculate

$$\begin{aligned}\widehat{R_\theta f}(\xi) &= \int_{-\infty}^{\infty} e^{-i\xi s} R_\theta f(s) ds \\ &= \int_{-\infty}^{\infty} e^{-i\xi s} \int_{-\infty}^{\infty} f(s\vec{\theta} + \tau\vec{\theta}^\perp) d\tau ds \\ &= \int_{\mathbb{R}^2} e^{-i\xi \vec{\theta} \cdot x} f(x) dx \\ &= \widehat{f}(\xi \vec{\theta}).\end{aligned}$$

□

Practically Dubious Theorem: Unique determination from limited-angle data

Let $f : \mathbb{R}^2 \rightarrow \mathbb{R}$ be smooth and compactly supported. Let $\varepsilon > 0$. Then f is uniquely determined from the limited-angle sinogram

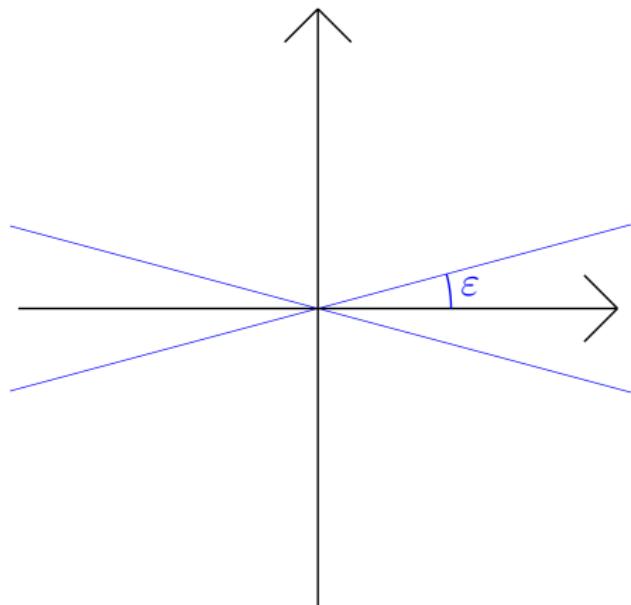

$$Rf(\theta, s) \quad \text{with } -\varepsilon < \theta < \varepsilon \text{ and } s \in \mathbb{R}.$$

Proof. Let f and g be compactly supported smooth functions defined on \mathbb{R}^2 satisfying $Rf(\theta, s) = Rg(\theta, s)$ for $-\varepsilon < \theta < \varepsilon$. By the Fourier slice theorem we know that

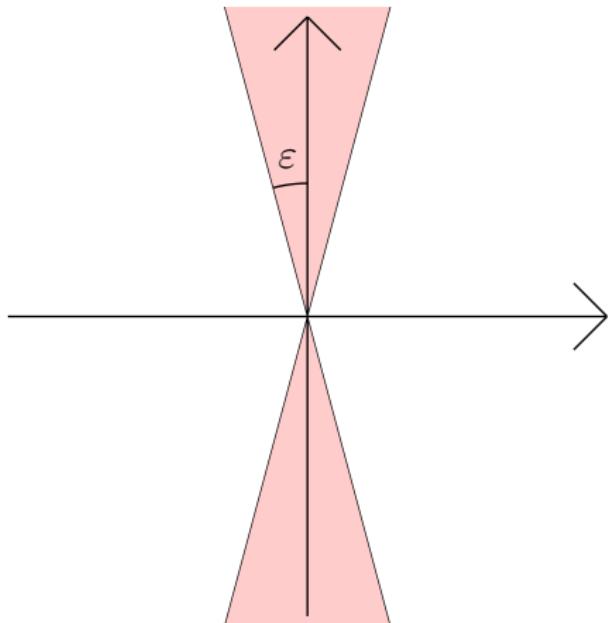

$$\hat{f}(\xi \vec{\theta}) \equiv \hat{g}(\xi \vec{\theta})$$

in the open set $C_\varepsilon := \{(\xi, \theta) \in \mathbb{R}^2 \mid \xi > 0, -\varepsilon < \theta < \varepsilon\}$. The Fourier transform of a compactly supported smooth function is analytic. So $\hat{f} = \hat{g}$ on the open set C_ε , and due to analyticity $\hat{f} = \hat{g}$ on the whole frequency domain \mathbb{R}^2 . Therefore $f \equiv g$. \square

Limited angle measurement information looks like a bowtie in the frequency domain

Range of measured angles is $(-\varepsilon, \varepsilon)$

Frequency domain

What do we know about the singular values of the Radon transform?

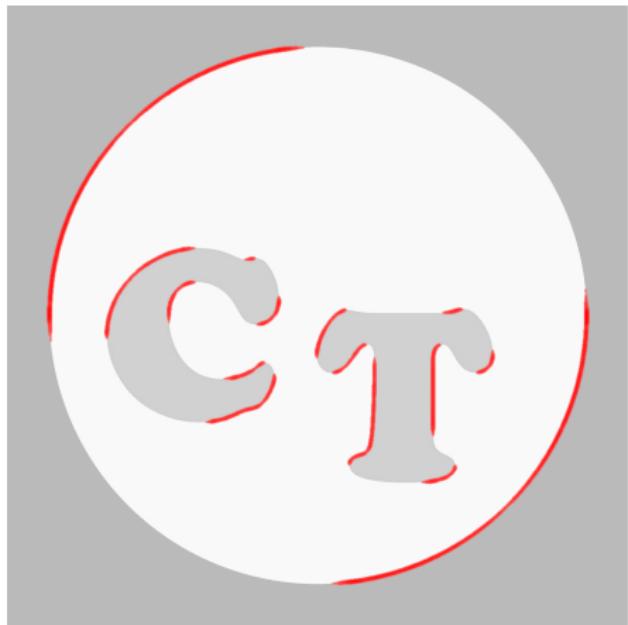

Roughly speaking,

- ▶ the full-angle Radon transform allows a singular system where the singular values decay as $d_n \sim 1/n$ when $n \rightarrow \infty$;
- ▶ the singular values of limited-angle Radon transform decay exponentially even if the interval of missing angles is just $(-\varepsilon, \varepsilon)$ with any $\varepsilon > 0$.

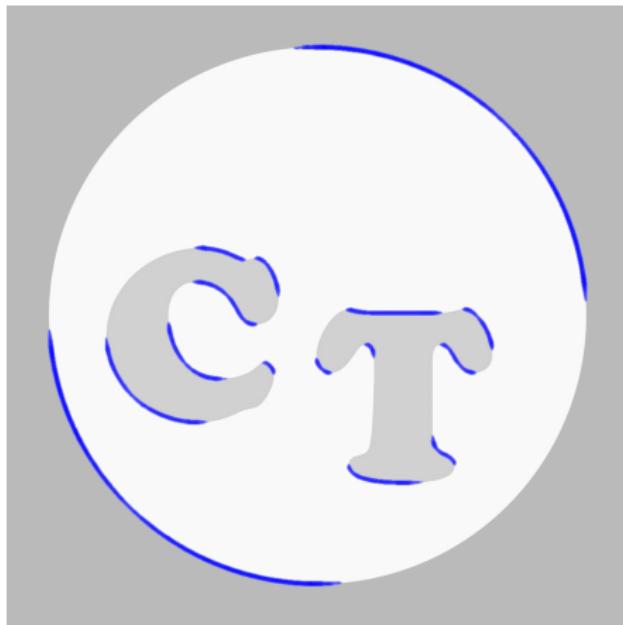

The details are available in Natterer 1986, Sections IV.3 and VI.2.

For more information, see Davison 1983 and Louis 1986.

Limited data gives only part of the wavefront set

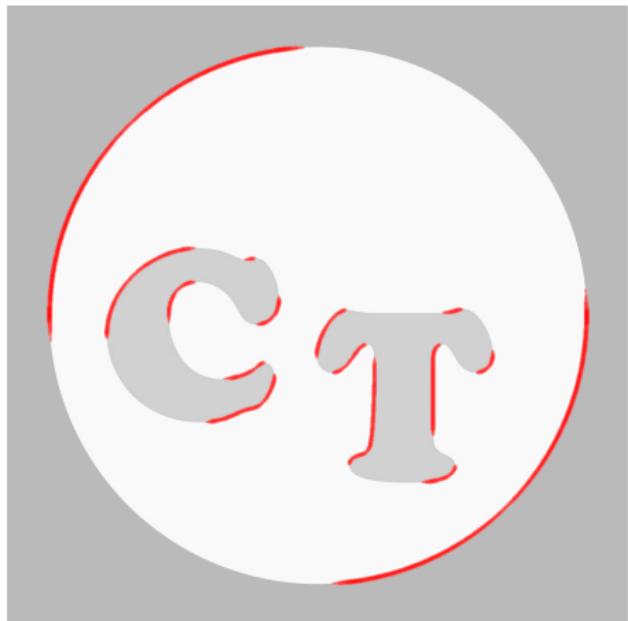

Stable part of wavefront set

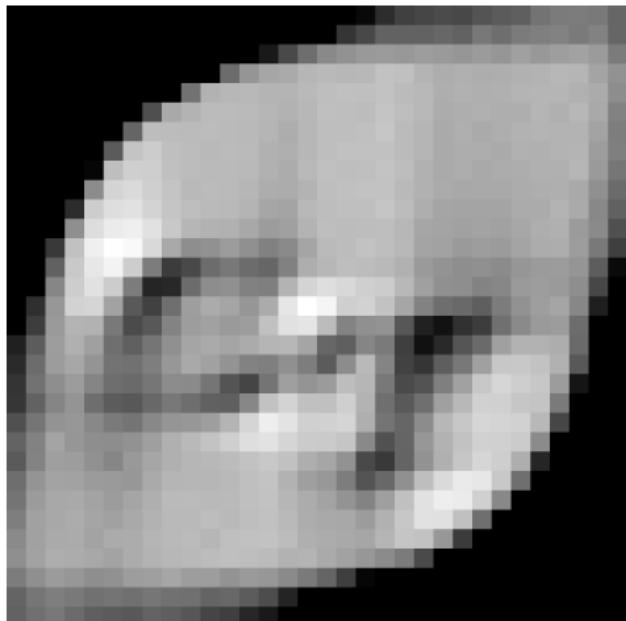

Unstable part of wavefront set

The Helsinki Tomography Challenge 2022

9 participating teams from 7 countries:

- Austria
- Brazil
- China
- Denmark
- Germany
- India
- Singapore

Altogether 22 different algorithms were submitted.

The Helsinki Tomography Challenge 2022

The top ranking teams are:

1. Technical University Dortmund, Department of Computer Science & Heinrich Heine University Düsseldorf, Department of Computer Science - Germany
2. University of Bremen, Center for Industrial Mathematics (ZeTeM) - Germany
3. Technical University of Denmark, Department of Applied Mathematics and Computer Science - Denmark

The full results are viewable at

https://fips.fi/HTC2022_results.pdf.

All the data and participating algorithms are openly available.

Scoring the quality of reconstructions

Reconstructed binary image is I_r , ground truth binary image is I_t .
The score of the reconstruction is given by the Matthews correlation coefficient (MCC). Define

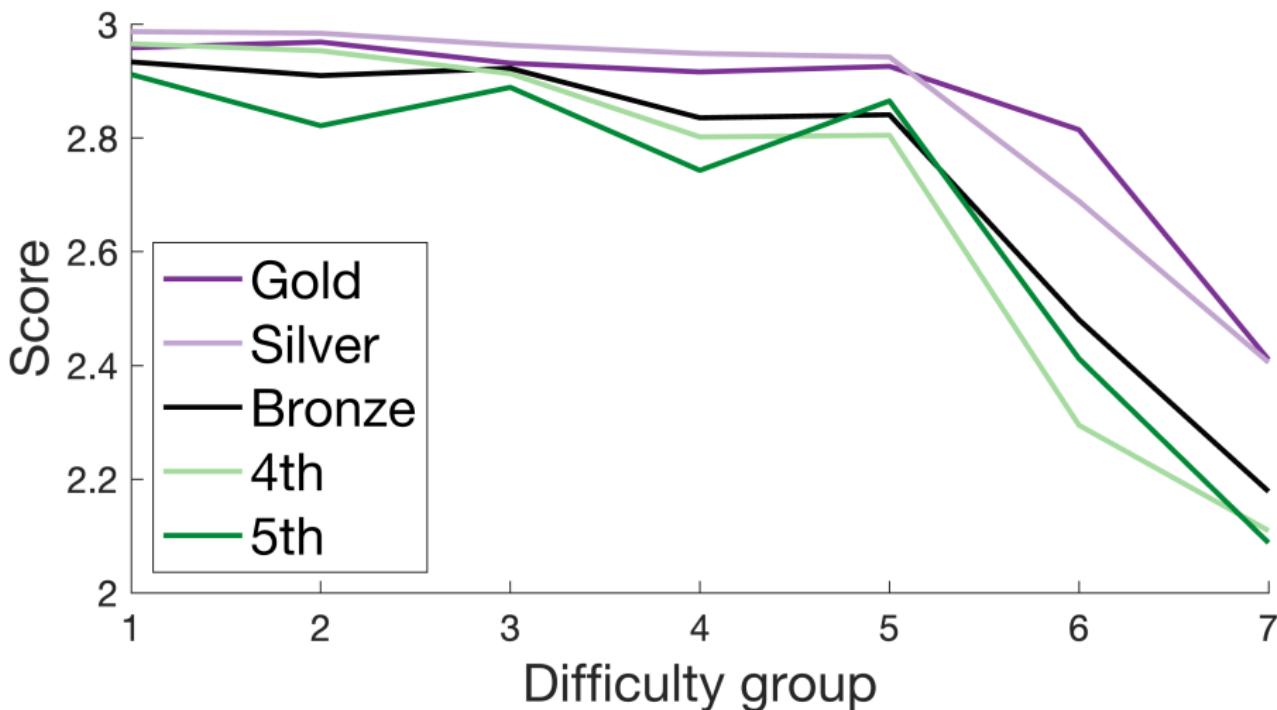

$$\begin{aligned} TP &= \sum_{i,j} (I_t \cap I_r)_{ij}, & FP &= \sum_{i,j} (\bar{I}_t \cap I_r)_{ij}, \\ FN &= \sum_{i,j} (I_t \cap \bar{I}_r)_{ij}, & TN &= \sum_{i,j} (\bar{I}_t \cap \bar{I}_r)_{ij}. \end{aligned}$$

Calculate MCC score $S \in [-1, 1]$ as

$$S = \frac{TP \times TN - FP \times FN}{\sqrt{(TP + FP)(TP + FN)(TN + FP)(TN + FN)}}.$$

A score of +1 (best) represents a perfect reconstruction, 0 no better than random reconstruction, and -1 (worst) indicates total disagreement between reconstruction and ground truth.

The scores of the five best teams in HTC2022
